(57) **ABSTRACT**

(52) **U.S. Cl.**
CPC **B63B 21/04** (2013.01)

A system for rope cleating is disclosed. A system incorporating teachings of the present disclosure may include a cleating component, an anchoring component, and an exterior shell. In practice, the system may facilitate connecting a boat to a dock even if the boater is unfamiliar with proper nautical knots.

ROPE CLEATING SYSTEM

This application claims priority to U.S. Provisional Patent Application No. 61/974,254 filed on Apr. 2, 2014 in the name of Russell W. White and Stanley M. Dufek entitled ROPE CLEATING SYSTEM.

TECHNICAL FIELD

The following disclosure relates to rope cleats, and more particularly to a rope cleating system.

BACKGROUND

Generally speaking, rope cleats facilitate the securing of a rope to or around an object. Often, a cleat is attached to a dock, and a person ties a rope that is connected to a boat around the cleat. One example is a double horn cleat to which a person typically ties a cleat hitch knot. However, many boaters do not know how to tie proper knots like the cleat hitch knot.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 illustrates an exploded view of a rope cleating system that incorporates teachings of the present disclosure for improved performance.

FIG. 2 depicts a photographic style image that depicts use of a rope cleating system that incorporates teachings of the present disclosure.

FIG. 3A illustrates a traditional double horned cleat with a rope secured using a cleat hitch knot.

FIG. 3B illustrates a traditional double horned cleat with a rope secured using an arbitrary knot that will not remain secure.

DETAILED DESCRIPTION

As mentioned above, a rope cleat can be used to facilitate the securing of a rope to or around an object. One type of cleat, the double horned cleat, can often be found on boat docks. In many cases, the cleat is bolted or screwed to a wooden dock and made available to docking boats. In such a circumstance, the docking boat may have a rope tied to some portion of the boat. The end of the rope that is not tied to the boat may be used to tether the boat to the dock by wrapping the rope around the double horned cleat. As shown in FIGS. 3A and 3B, there can be significant differences in the type of knot used to tie off to the cleat. FIG. 3A illustrates a traditional double horned cleat with a rope secured using a cleat hitch knot. The knot depicted in FIG. 3A is an effective knot and should keep a tethered boat securely connected to the dock. FIG. 3B illustrates a traditional double horned cleat with a rope secured using an arbitrary knot that will not remain secure.

Many boaters lack the knot tying expertise necessary to safely secure a boat to an available double horned cleat. The cleating systems depicted in FIGS. 1 and 2, in addition to other potential benefits, could help these boaters to safely secure their boats to available docks. As mentioned above, FIG. 1 illustrates an exploded view of a rope cleating system 100 that incorporates teachings of the present disclosure for improved performance. As shown, system 100 includes a cleating sleeve 102, an anchoring sleeve 104, and a floating shell 106. Though system 100 is depicted in an exploded manner, one skilled in the art will recognize how system 100 may be connected into a unit. Moreover, one skilled in the art

2

will recognize that the three-piece system could also be manufactured as a one-piece or a two-piece system. Similarly, a designer may elect to utilize a system with more than three pieces.

As shown, cleating sleeve 102 defines a generally elliptical opening 108 through which a rope may be doubled back upon itself. Cleating sleeve 102 also includes a member 109 and an end cap 110 that defines a shoulder 112 that may serve to help keep floating shell 106 in position when cleating sleeve 102 and anchoring sleeve 104 are connected. Cleating sleeve also includes a cleat opening 114 that defines three cleating locations indicated generally at 116. In practice, a rope may pass through elliptical opening 108 (along the bottom of the opening), around anchoring sleeve 104 (as defined more fully below) and back through elliptical opening 108 (this time above the earlier passed rope). The tag end of the rope routed in such a way may then be pulled into cleat opening 114 and removably locked in place.

Cleating sleeve 102 also includes locking port 116, which may interact with locking node 118 to help secure cleating sleeve 102 to anchoring sleeve 104. In some instances, locking port 116 and locking node 118 may releasably connect sleeves 102 and 104. For example, a designer may offer system 100 as a kit with more than one anchoring sleeves like sleeve 104. Each of the sleeves included in such a kit may be sized for use with different diameters of rope. If a boater is using $\frac{3}{8}$ inch rope, the boater may use an anchoring sleeve designed for $\frac{3}{8}$ to $\frac{1}{2}$ inch rope (for example). If the boater is using $\frac{5}{8}$ inch rope, the boater may upsize to an anchoring sleeve designed for ropes larger than $\frac{1}{2}$ inch.

As shown, anchoring sleeve 104 includes a dual port system 120, which may allow for a separation of the rope as it passes into and out of anchoring sleeve 104. Dual port system 120 (as depicted) extends through member 121 and includes deflection slits 122, which facilitate the sliding of anchoring sleeve 104 or at least a portion of sleeve 104 into cleating sleeve 102. In addition, deflection slits 122 may create a spring force that helps lock depicted locking node 118 into locking port 116. Anchoring sleeve 104 may also include an end cap 124 that acts in a manner similar to end cap 110.

As shown, dual port system 120 may include two holes that remain independent from one another and are formed all the way through anchoring sleeve 104. Such a design may keep a rope passed through the bottom hole and then routed back through the top hole from being “pulled through” and accidentally removed from system 100. As shown, the holes of anchoring sleeve 104 may be specifically designed for a given diameter of rope. The holes may also be designed with some “slop” to allow for some flexibility in the diameter of rope used. For example, the holes may allow for the sliding through of a rope having a $\frac{3}{8}$ inch diameter, a $\frac{1}{2}$ inch diameter, or both.

System 100, as depicted, also includes floating shell 106, which surrounds cleating sleeve 102 and anchoring sleeve 104 when system 100 is snapped together. Though floating shell 106, as depicted, is intended to provide buoyancy and to help system 100 float when in use, a given designer may choose to create floating shell 106 from a material that does not float. As shown, floating shell 106 is intended to float and to provide some give or impact resistance. As such, floating shell 106 may be formed from several different materials. For example, floating shell 106 may be formed from neoprene, sponge, foam, rubber, plastic, some other lightweight material, and/or a combination of materials. Similarly, cleating sleeve 102 and anchoring sleeve 104 may be formed from the same or different materials. In one example version of system 100, cleating sleeve 102 and anchoring sleeve 104 may be

3

formed from an extruded plastic material while floating shell **106** may be formed from a scuba foam, a fabric, a foam, a neoprene, or other high buoyancy material that facilitates screen printing on its exterior surface.

As depicted, floating shell **106** is sized to fit snugly around cleating sleeve **102** and anchoring sleeve **104** and to be held in place by end caps **110** and **124** when cleating sleeve **102** and anchoring sleeve **104** are connected to one another. In addition, floating shell **106** includes cut out **126**, which may help a user to pull the tag end of a rope into cleat opening **114** without undue interference from floating shell **106**. As shown, the generally elliptical cross section of cleating sleeve **102**, anchoring sleeve **104**, and the hole **128** formed through floating shell **106** may help to keep cut out **126** in position relative to cleat opening **114**. In addition, a designer may elect to include a printable location **130** on shell **106** to facilitate the inclusion of marketing, branding, and/or contact information, some or all of which may be printed and/or reproduced on shell **106**.

As indicated above, system **100** incorporates teachings of the present disclosure and represents one way a designer may choose to implement some teachings. Many things could be altered if a designer so chooses without departing from the present teachings. As mentioned above, the number of component parts within system **100** may be changed. Similarly, different materials may be chosen. Components of a system like system **100** may include, for example, one or more of a plastic material, a rubber material, a spandex material, a leather material, a neoprene material, a metal material, a wooden material, a woven material, and/or some other material that is suitable for performing the objectives of system **100**.

As indicated above, FIG. 2 depicts a photographic style image of a rope cleating solution **200** that incorporates teachings of the present disclosure. As shown, a system **202**, which may be like system **100**, is shown in an assembled state. In addition, a rope **204** is shown as passing through system **202** around double homed cleat **206** and back through system **202**. Rope **204**, as depicted, has been seated into a cleating mechanism **208**, which may be similar to cleat opening **114**. The tag end **210** of rope **204** is shown as resting on a wooden dock **212** to which double homed cleat **206** is attached.

System **202** also depicts an outer shell **214**, which may be similar to floating shell **106**. As shown, outer shell **214** presents a printable surface **216** onto which the words "SeaRay" and "www.searay.com" are printed. The printing technique may include, for example, silk screen printing, embossing, branding, labeling, stamping, embroidering, etc., and/or some combination of these or other techniques. As shown, printable surface **216** may be made from a material and offered in a size and shape that facilitates the inclusion of branding, marketing, and/or contact information, among other things.

In one offering, a system, like system **202**, may work with various standard rope diameters, may be made of some combination of soft, durable, and/or floating materials, and may provide a surface to add marketing and contact information. Such a system may, for example, help boaters who tie knots like the one depicted in FIG. 3B to safely and securely tether their boats to docks with double horned cleats.

A system incorporating teachings of the present disclosure may replace, add, or delete many of the above-described

4

features and components without departing from the scope of the disclosure. One skilled in the art will recognize that the many of the above-described components could be combined or broken out into other combinations.

Although the present invention has been described in detail, it should be understood that various changes, substitutions and alterations to the devices, methods, and other aspects and techniques of the present invention can be made without departing from the spirit and scope of the invention as defined by the appended claims.

While the present invention has been described with respect to a limited number of embodiments, those skilled in the art will appreciate numerous modifications and variations therefrom. It is intended that the appended claims cover all such modifications and variations as fall within the true spirit and scope of this present invention.

What is claimed is:

1. A system comprising:

a cleating component formed of plastic and including a first end cap at least partially defining a U-shaped void, a member extending from one side of the end cap and having a generally elliptical cross section, the member formed to at least partially define an elliptical void formed along a longitudinal axis of the member, a cleat opening at least partially defined by an open end of the U-shaped void and a cut away in the member, and a locking port;

an anchoring component formed of plastic and including a second end cap at least, a dual port member extending from one side of the second end cap and having a generally elliptical cross section, the dual port member formed to at least partially define a first and second generally circular voids formed along a longitudinal axis of the dual port member, a deflection slit cut into at least a portion of the dual port member, and a locking node; and

a floating shell formed of a foam material and including a cut away region, a generally elliptical void formed along its longitudinal, access, and a printing location on an exterior portion of the floating shell.

2. The system of claim 1, wherein the cleating component comprises a cleating sleeve.

3. The system of claim 1, wherein the cleat opening defines a plurality of cleating locations.

4. The system of claim 1, wherein the locking port is to interact with the locking node to secure the cleating component to the anchoring component.

5. The system of claim 4, wherein the locking port and the locking node are to releasably connect the cleating component and the anchoring component.

6. The system of claim 1, wherein the anchoring component comprises an anchoring sleeve.

7. The system of claim 1, wherein the deflection slit is to facilitate sliding of at least a portion of the anchoring component into the cleating component.

8. The system of claim 1, wherein the first and second generally circular voids comprise independent openings to enable a rope to slide there through.
